Welcome to the first project of CS 162! Our projects in this class will use Pintos, an educational operating system. They designed to give you practical experience with the central ideas of operating systems in the context of developing a real, working kernel, without being excessively complex. The skeleton code for Pintos has several limitations in its file system, thread scheduler, and support for user programs. In the course of these projects, you will greatly improve Pintos in each of these areas.

Our project specifications in CS 162 will be organized as follows. For clarity, the details of the assignment itself will be in the Your Task section at the start of the document. We will also provide additional material in the Reference section that will hopefully be useful as you design and implement a solution to the project. You may find it useful to begin with the Reference section for an overview of Pintos before trying to understand all of the details of the assignment in Your Task.

1 Setup

"/code/group will be the directory that contains the group skeleton code and the folder where you will be working on the projects in this class. If you don't see the "/code/group directory inside your VM or are having issues with pushing and pulling code from GitHub, here's how to set it up.

1.1 Group Repository Setup

Here's how to create the group folder if you don't have one (if you do, run cd ~/code/group and skip to Step 2), and add the two remotes (one called group, which will point to your group's GitHub repository, and one which will be called staff, which will point to the group0 branch) by doing the following steps in your VM:

1. Run the following commands to create the group folder and attach it to the GitHub Repo:

```
git clone https://github.com/Berkeley-CS162/group0.git ~/code/group
cd ~/code/group/
```

- 2. Then visit your group repo on GitHub and find the SSH clone URL. It should have the form "gitQgithub.com:Berkeley-CS162/..."
- 3. Now run the following commands to add the remotes

```
git remote add group YOUR_GITHUB_CLONE_URL
git remote add staff https://github.com/Berkeley-CS162/groupO.git
```

4. If you would like to set the origin remote to your group's branch, please run the following:

```
git remote set-url origin YOUR_GROUP_GITHUB_CLONE_URL
```

5. You can get information about the remote you just added

```
git remote -v
git remote show group
```

6. Fetch the latest skeleton code by running the following

```
git pull staff master
```

7. Install the pre-commit hook

```
sudo apt install clang-format
ln -s -f ../../.pre-commit.sh .git/hooks/pre-commit
```

2 Your Task

In this project, you will extend Pintos's support for user programs. The skeleton code for Pintos is already able to load user programs into memory, but the programs cannot read command-line arguments or make system calls.

2.1 Task 1: Argument Passing

The "process_execute(char *file_name)" function is used to create new user-level processes in Pintos. Currently, it does not support command-line arguments. You must implement argument passing, so that calling "process_execute("ls -ahl")" will provide the 2 arguments, ["ls", "-ahl"], to the user program using argc and argv.

Many of our Pintos test programs start by printing out their own name (e.g. argv[0]). Since argument passing has not yet been implemented, all of these programs will crash when they access argv[0]. Until you implement argument passing, these user programs will not work.

2.2 Task 2: Process Control Syscalls

Pintos currently only supports one syscall: exit. You will add support for the following new syscalls: practice, halt, exec, and wait. Each of these syscalls has a corresponding function inside the user-level library in pintos/src/lib/user/syscall.c¹, which prepares the syscall arguments and handles the transfer to kernel mode. The kernel's syscall handler is located in pintos/src/userprog/syscall.c².

The practice syscall just adds 1 to its first argument, and returns the result (to give you practice writing a syscall handler). The halt syscall will shut down the system. The exec syscall will start a new program with process_execute(). (There is no fork syscall in Pintos. The Pintos exec syscall is similar to calling Linux's fork syscall and then Linux's execve syscall in the child process immediately afterward.) The wait syscall will wait for a specific child process to exit.

To implement syscalls, you first need a way to safely read and write memory that's in user process's virtual address space. The syscall arguments are located on the user process's stack, right above the user process stack pointer. You are not allowed to have the kernel crash while trying to dereference an invalid or null pointer. For example, if the stack pointer is invalid when the user program makes a syscall, the kernel ought not crash when trying to read syscall arguments from the stack. Additionally, some syscall arguments are pointers to buffers inside the user process's address space. Those buffer pointer could be invalid as well.

You will need to gracefully handle cases where a syscall cannot be completed, because of invalid memory access. These kinds of memory errors include null pointers, invalid pointers (which point to unmapped memory locations), or pointers to the kernel's virtual address space. Beware: a 4-byte memory region (like a 32-bit integer) may consist of 2 bytes of valid memory and 2 bytes of invalid memory, if the memory lies on a page boundary. You should handle these cases by terminating the user process. We recommend testing this part of your code before implementing any other system call functionality. See Accessing User Memory for more information.

 $^{^{1} \}rm https://github.com/Berkeley-CS162/group0/blob/master/pintos/src/lib/user/syscall.c$

 $^{^2} https://github.com/Berkeley-CS162/group0/blob/master/pintos/src/userprog/syscall.c$

2.3 Task 3: File Operation Syscalls

In addition to the process control syscalls, you will also need to implement these file operation syscalls: create, remove, open, filesize, read, write, seek, tell, and close. Pintos already contains a basic file system. Your implementation of these syscalls will simply call the appropriate functions in the file system library. You will not need to implement any of these file operations yourself.

The Pintos file system is not thread-safe. You must make sure that your file operation syscalls do not call multiple file system functions concurrently. In Project 3, you will add more sophisticated synchronization to the Pintos file system, but for this project, you are permitted to use a global lock on file system operations, treating the entire file system code as a single critical section to ensure thread safety. We recommend that you avoid modifying the filesys/ directory in this project.

While a user process is running, you must ensure that nobody can modify its executable on disk. The "rox" tests ensure that you deny writes to current-running program files. The functions file_deny_write() and file_allow_write() can assist with this feature. Denying writes to executables backing live processes is important because an operating system may load code pages from the file lazily, or may page out some code pages and reload them from the file later. In Pintos, this is technically not a concern because the file is loaded into memory in its entirety before execution begins, and Pintos does not implement demand paging of any sort. However, you are still required to implement this, as it is good practice.

Note: Your final code for Project 1 will be used as a starting point for Project 3. The tests for Project 3 depend on some of the same syscalls that you are implementing for this project, and you may have to modify your implementations of some of these syscalls to support additional features required for Project 3. You should keep this in mind while designing your implementation for this project.

3 Deliverables

Your project grade will be made up of 4 components:

- 15% Design Document and Design Review
- 75% Code and Student Testing
- 10% Final Report and Code Quality

3.1 Design Document (Due 09/18 @ 11:59 PM PDT) and Design Review

Before you start writing any code for your project, you should create an implementation plan for each feature and convince yourself that your design is correct. For this project, you must **submit a design document** and **attend a design review** with your project TA.

Submit your design document as a PDF to the Project 1 Design Document assignment on Gradescope. There are two parts to the design document. The first part is a Design Overview where you will include an overview of your proposed design for completing Project 1. The third part is to answer some Additional Questions. We explain each part of the design document in detail in the sections below.

3.1.1 Design Overview

For each of the 3 tasks of this project, you must explain the following 4 aspects of your proposed design. We suggest you create a section for each of the 3 project parts. Then, in each section, create subsections for each of these 4 aspects.

1. **Data structures and functions** – Write down any struct definitions, global (or static) variables, typedefs, or enumerations that you will be adding or modifying (if it already exists). These definitions should be written with the **C programming language**, not with pseudocode. Include

a **brief explanation** the purpose of each modification. Your explanations should be as concise as possible. Leave the full explanation to the following sections.

- 2. Algorithms This is where you tell us how your code will work. Your description should be at a level below the high level description of requirements given in the assignment. We have read the project spec too, so it is unnecessary to repeat or rephrase what is stated here. On the other hand, your description should be at a level above the code itself. Don't give a line-by-line run-down of what code you plan to write. Instead, you should try to convince us that your design satisfies all the requirements, including any uncommon edge cases. We expect you to read through the Pintos source code when preparing your design document, and your design document should refer to the Pintos source when necessary to clarify your implementation.
- 3. Synchronization This section should list all resources that are shared across threads. For each case, enumerate how the resources are accessed (e.g., from an interrupt context, etc), and describe the strategy you plan to use to ensure that these resources are shared and modified safely. For each resource, demonstrate that your design ensures correct behavior and avoids deadlock. In general, the best synchronization strategies are simple and easily verifiable. If your synchronization strategy is difficult to explain, this is a good indication that you should simplify your strategy. Please discuss the time/memory costs of your synchronization approach, and whether your strategy will significantly limit the concurrency of the kernel and/or user processes. When discussing the parallelism allowed by your approach, explain how frequently threads will contend on the shared resources, and any limits on the number of threads that can enter independent critical sections at a single time. You should aim to avoid locking strategies that are overly coarse.
- 4. **Rationale** Tell us why your design is better than the alternatives that you considered, or point out any shortcomings it may have. You should think about whether your design is easy to conceptualize, how much coding it will require, the time/space complexity of your algorithms, and how easy/difficult it would be to extend your design to accommodate additional features.

3.1.2 Additional Questions

You must also answer these additional questions in your design document:

- 1. Take a look at the Project 1 test suite in pintos/src/tests/userprog. Some of the test cases will intentionally provide invalid pointers as syscall arguments, in order to test whether your implementation safely handles the reading and writing of user process memory. Please identify a test case that uses an invalid stack pointer (%esp) when making a syscall. Provide the name of the test and explain how the test works. (Your explanation should be very specific: use line numbers and the actual names of variables when explaining the test case.)
- 2. Please identify a test case that uses a **valid** stack pointer when making a syscall, but the stack pointer is too close to a page boundary, so some of the syscall arguments are located in invalid memory. (Your implementation should kill the user process in this case.) Provide the name of the test and explain how the test works. (Your explanation should be very specific: use line numbers and the actual names of variables when explaining the test case.)
- 3. Identify **one** part of the project requirements which is **not fully tested by the existing test suite**. Explain what kind of test needs to be added to the test suite, in order to provide coverage for that part of the project. (There are multiple good answers for this question.)

3.1.3 Design Review

You will schedule a 20-30 minute design review with your project TA. During the design review, your TA will ask you questions about your design for the project. You should be prepared to defend your

design and answer any clarifying questions your TA may have about your design document. The design review is also a good opportunity to get to know your TA for those participation points.

3.1.4 Grading

The design document and design review will be graded together. Your score will reflect how convincing your design is, based on your explanation in your design document and your answers during the design review. You **must** attend a design review in order to get these points. We will try to accommodate any time conflicts, but you should let your TA know as soon as possible.

3.2 Code (Due 09/24, 10/02, 10/05 @ 11:59 PM PDT)

The code section of your grade will be determined by your autograder score. Pintos comes with a test suite that you can run locally on your VM. We run the same tests on the autograder. The results of these tests will determine your code score. Be sure to push your code to GitHub for the checkpoints, and the final code. This is how we will track your progress for the checkpoints.

You can check your current grade for the code portion at any time by logging in to the course autograder. Autograder results will also be emailed to you.

We will check your progress on Project 1 at two intermediate checkpoints. **These checkpoints will not be counted towards the final grade for your project.** However, it is in your best interest to complete them to ensure that your group is on pace to finish the assignment. Our goal is not to grade your in-progress implementations, but to ensure that you're making satisfactory progress and encourage you to ask for help early and often.

3.3 Checkpoint #1 (Due 09/24) [Ungraded]

You must have implemented the following:

- The write syscall for the STDOUT file descriptor only.
- The practice syscall.
- Task 1: Argument Passing in its entirety.

We recommend that you begin the project by implementing the write syscall for the STDOUT file descriptor. Once you've done this, the stack-align-1 test should pass, assuming you build on the code you have at the end of Project 0, and you properly align the stack when no command line arguments are passed to the user program.

After you've completed the above task and printf() works from userspace, implement the practice syscall and argument passing.

As a final step, make sure that the exit(-1) message is printed even if a process exits due to a fault. Currently the exit code is printed³ when the exit syscall is made from userspace, but not if it the process exits due to an invalid memory access.

3.4 Checkpoint #2 (Due 10/02) [Ungraded]

In addition to the tasks in Checkpoint #1 (Due 09/24) [Ungraded], you must have completed Task 2: Process Control Syscalls in its entirety.

3.5 Final Code (Due 10/05 @ 11:59 PM PDT)

You must have completed the entire project: Task 1: Argument Passing, Task 2: Process Control Syscalls, and Task 3: File Operation Syscalls.

 $^{^3} https://github.com/Berkeley-CS162/group0/blob/master/pintos/src/userprog/syscall.c\#L25$

3.5.1 Student Testing Code (Due 10/05 @ 11:59 PM PDT)

Pintos already contains a test suite for Project 1, but not all of the parts of this project have complete test coverage. Your task is to submit 2 new test cases, which exercise functionality that is not covered by existing tests. We will not tell you what features to write tests for. You will be responsible for identifying which features of this project would benefit most from additional tests. Make sure your own project implementation passes the tests that you write. You can pick any appropriate name for your test, but beware that test names should be no longer than 14 characters. Once you finish writing your test cases, make sure that they get executed when you run "make check" in the pintos/src/userprog/ directory.

3.6 Student Testing Report (Due 10/07 @ 11:59 PM PDT)

While the tests themselves must be submitted with the rest of your code, you will also need to prepare a Student Testing Report, which will help us grade your test cases. Include your student testing report as a section in the same PDF as the rest of your final report (described in the next section).

Make sure your Student Testing Report contains the following:

- For each of the 2 test cases you write:
 - Provide a description of the feature your test case is supposed to test.
 - Provide an overview of how the mechanics of your test case work, as well as a qualitative description of the expected output.
 - Provide the output of your own Pintos kernel when you run the test case. Please copy the full raw output file from userprog/build/tests/userprog/your-test-1.output as well as the raw results from userprog/build/tests/userprog/your-test-1.result.
 - Identify two non-trivial potential kernel bugs, and explain how they would have affected your output of this test case. You should express these in this form: "If your kernel did X instead of Y, then the test case would output Z instead.". You should identify two different bugs per test case, but you can use the same bug for both of your two test cases. These bugs should be related to your test case (e.g. "If your kernel had a syntax error, then this test case would not run." does not count).
- Tell us about your experience writing tests for Pintos. What can be improved about the Pintos testing system? (There's a lot of room for improvement.) What did you learn from writing test cases?

We will grade your test cases based on effort. If all of the above components are present in your Student Testing Report and your test cases are satisfactory, you will get full credit on this part of the project.

3.7 Final Report (Due 10/07 @ 11:59 PM PDT) and Code Quality

After you complete the code for your project, your group will submit a final report in the form of a PDF to the Project 1 Final Report assignment on Gradescope. Please include the following in your final report:

- The changes you made since your initial design document and why you made them (feel free to re-iterate what you discussed with your TA in the design review)
- A reflection on the project what exactly did each member do? What went well, and what could be improved?

• Your Student Testing Report (see the previous section for more details).

You will also be graded on the quality of your code. This will be based on many factors:

- Does your code exhibit any major memory safety problems (especially regarding C strings), memory leaks, poor error handling, or race conditions?
- Is your code simple and easy to understand? Does it follow a consistent naming convention?
- If you have very complex sections of code in your solution, did you add enough comments to explain them?
- Did you leave commented-out code in your final submission?
- Did you copy-paste code instead of creating reusable functions?
- Did you re-implement linked list algorithms instead of using the provided list manipulation
- Is your Git commit history full of binary files? (don't commit object files or log files for this project)

Note that you don't have to worry about manually enforcing code formatting (e.g. indentation, spacing, wrapping long lines, consistent placement of braces, etc.) as the make rule make format (which is run automatically each time you commit provided you followed the setup instructions correctly) takes care of this.

4 Reference

The majority of the PintOS reference is now located in the specification for Project 0, "Introduction to Pintos" in an effort to keep this project specification from being intimidatingly long. Please be sure to go through it.

We have copied here the User Programs section because it is useful for both Project 0 and Project 1. Additionally, you will need to carefully read through the System Calls section (which is *not* included in the Project 0 Reference) as it details the required behavior of the syscalls you will implement for this project.

4.1 User Programs

User programs are written under the illusion that they have the entire machine, which means that the operating system must manage/protect machine resources correctly to maintain this illusion for multiple processes. In Pintos, more than one process can run at a time, but each process is single-threaded (multithreaded processes are not supported).

4.1.1 Overview of Source Files for Project 1

threads/thread.h Contains the struct thread definition, which is the Pintos thread control block.

The fields in #ifdef USERPROG ... #endif are collectively the process control block. We expect that you will add fields to the process control block in this project.

userprog/process.c Loads ELF binaries, starts processes, and switches page tables on context switch.

userprog/pagedir.c Manages the page tables. You probably won't need to modify this code, but you may want to call some of these functions.

userprog/syscall.c This is a skeleton system call handler. Currently, it only supports the exit syscall.

lib/user/syscall.c Provides library functions for user programs to invoke system calls from a C program. Each function uses inline assembly code to prepare the syscall arguments and invoke the system call. We do expect you to understand the calling conventions used for syscalls (also in Reference).

lib/syscall-nr.h This file defines the syscall numbers for each syscall.

- userprog/exception.c Handle exceptions. Currently all exceptions simply print a message and terminate the process. Some, but not all, solutions to Project 1 involve modifying page_fault() in this file.
- gdt.c 80x86 is a segmented architecture. The Global Descriptor Table (GDT) is a table that describes the segments in use. These files set up the GDT. You should not need to modify these files for any of the projects. You can read the code if you're interested in how the GDT works.
- tss.c The Task-State Segment (TSS) is used for 80x86 architectural task switching. Pintos uses the TSS only for switching stacks when a user process enters an interrupt handler, as does Linux. You should not need to modify these files for any of the projects. You can read the code if you're interested in how the TSS works.

4.1.2 How User Programs Work

Pintos can run normal C programs, as long as they fit into memory and use only the system calls you implement. Notably, malloc cannot be implemented because none of the system calls required for this project allow for memory allocation. Pintos also can't run programs that use floating point operations, since the kernel doesn't save and restore the processor's floating-point unit when switching threads.

The src/examples directory contains a few sample user programs. The Makefile in this directory compiles the provided examples, and you can edit it to compile your own programs as well. Pintos can load *ELF* executables with the loader provided for you in userprog/process.c.

Until you copy a test program to the simulated file system (see "Formatting and Using the File System" in the reference section of Project 0), Pintos will be unable to do useful work. You should create a clean reference file system disk and copy that over whenever you trash your filesys.dsk beyond a useful state, which may happen occasionally while debugging.

4.1.3 Virtual Memory Layout

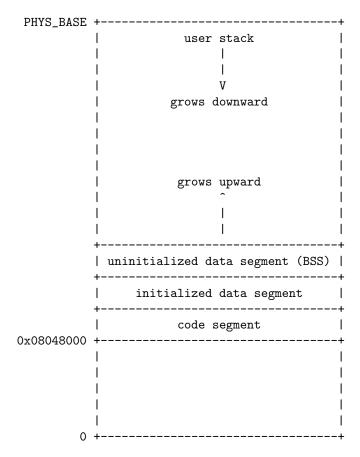

Virtual memory in Pintos is divided into two regions: user virtual memory and kernel virtual memory. User virtual memory ranges from virtual address 0 up to PHYS_BASE, which is defined in threads/vaddr.h and defaults to 0xc0000000 (3 GB). Kernel virtual memory occupies the rest of the virtual address space, from PHYS_BASE up to 4 GB.

User virtual memory is per-process. When the kernel switches from one process to another, it also switches user virtual address spaces by changing the processor's page directory base register (see pagedir_activate() in userprog/pagedir.c). struct thread contains a pointer to a process's page table.

Kernel virtual memory is global. It is always mapped the same way, regardless of what user process or kernel thread is running. In Pintos, kernel virtual memory is mapped one-to-one to physical memory, starting at PHYS_BASE. That is, virtual address PHYS_BASE accesses physical address 0, virtual address PHYS_BASE + 0x1234 accesses physical address 0x1234, and so on up to the size of the machine's physical memory.

A user program can only access its own user virtual memory. An attempt to access kernel virtual memory causes a page fault, handled by page_fault() in userprog/exception.c, and the process will be terminated. Kernel threads can access both kernel virtual memory and, if a user process is running, the user virtual memory of the running process. However, even in the kernel, an attempt to access memory at an unmapped user virtual address will cause a page fault.

Typical Memory Layout Conceptually, each process is free to lay out its own user virtual memory however it chooses. In practice, user virtual memory is laid out like this:

4.1.4 Accessing User Memory

As part of a system call, the kernel must often access memory through pointers provided by a user program. The kernel must be very careful about doing so, because the user can pass a null pointer, a pointer to unmapped virtual memory, or a pointer to kernel virtual address space (above PHYS_BASE). All of these types of invalid pointers must be rejected without harm to the kernel or other running processes, by terminating the offending process and freeing its resources.

There are at least two reasonable ways to do this correctly:

- verify the validity of a user-provided pointer, then dereference it. If you choose this route, you'll want to look at the functions in userprog/pagedir.c and in threads/vaddr.h. This is the simplest way to handle user memory access.
- check only that a user pointer points below PHYS_BASE, then dereference it. An invalid user pointer will cause a "page fault" that you can handle by modifying the code for page_fault() in userprog/exception.c. This technique is normally faster because it takes advantage of the processor's MMU, so it tends to be used in real kernels (including Linux).

In either case, you need to make sure not to "leak" resources. For example, suppose that your system call has acquired a lock or allocated memory with malloc(). If you encounter an invalid user pointer

afterward, you must still be sure to release the lock or free the page of memory. If you choose to verify user pointers before dereferencing them, this should be straightforward. It's more difficult to handle if an invalid pointer causes a page fault, because there's no way to return an error code from a memory access. Therefore, for those who want to try the latter technique, we'll provide a little bit of helpful code:

```
/* Reads a byte at user virtual address UADDR.
   UADDR must be below PHYS_BASE.
   Returns the byte value if successful, -1 if a segfault
   occurred. */
static int
get_user (const uint8_t *uaddr)
  int result;
  asm ("movl $1f, %0; movzbl %1, %0; 1:"
       : "=&a" (result) : "m" (*uaddr));
 return result;
}
/* Writes BYTE to user address UDST.
   UDST must be below PHYS BASE.
   Returns true if successful, false if a segfault occurred. */
static bool
put_user (uint8_t *udst, uint8_t byte)
  int error_code;
  asm ("movl $1f, %0; movb %b2, %1; 1:"
       : "=&a" (error_code), "=m" (*udst) : "q" (byte));
 return error_code != -1;
}
```

Each of these functions assumes that the user address has already been verified to be below PHYS_BASE. They also assume that you've modified page_fault() so that a page fault in the kernel merely sets eax to 0xffffffff and copies its former value into eip.

If you do choose to use the second option (rely on the processor's MMU to detect bad user pointers), do not feel pressured to use the <code>get_user</code> and <code>put_user</code> functions from above. There are other ways to modify the page fault handler to identify and terminate processes that pass bad pointers as arguments to system calls, some of which are simpler and faster than using <code>get_user</code> and <code>put_user</code> to handle each byte.

4.1.5 80x86 Calling Convention

This section summarizes important points of the convention used for normal function calls on 32-bit 80x86 implementations of Unix. Some details are omitted for brevity.

The calling convention works like this:

1. The caller pushes each of the function's arguments on the stack one by one, normally using the push assembly language instruction. Arguments are pushed in right-to-left order.

The stack grows downward: each push decrements the stack pointer, then stores into the location it now points to, like the C expression *--sp = value.

- 2. The caller pushes the address of its next instruction (the *return address*) on the stack and jumps to the first instruction of the callee. A single 80x86 instruction, call, does both.
- 3. The callee executes. When it takes control, the stack pointer points to the return address, the first argument is just above it, the second argument is just above the first argument, and so on.
- 4. If the callee has a return value, it stores it into register eax.
- 5. The callee returns by popping the return address from the stack and jumping to the location it specifies, using the 80x86 ret instruction.
- 6. The caller pops the arguments off the stack.

Consider a function f() that takes three int arguments. This diagram shows a sample stack frame as seen by the callee at the beginning of step 3 above, supposing that f() is invoked as f(1, 2, 3). The initial stack address is arbitrary:

```
0xbffffe7c | 3 |
0xbffffe78 | 2 |
0xbffffe74 | 1 |
stack pointer --> 0xbffffe70 | return address |
```

4.1.6 Program Startup Details

The Pintos C library for user programs designates _start(), in lib/user/entry.c, as the entry point for user programs. This function is a wrapper around main() that calls exit() if main() returns:

```
void
_start (int argc, char *argv[])
{
  exit (main (argc, argv));
}
```

The kernel must put the arguments for the initial function on the stack before it allows the user program to begin executing. The arguments are passed in the same way as the normal calling convention (see 80x86 Calling Convention).

Consider how to handle arguments for the following example command: /bin/ls -l foo bar. First, break the command into words: /bin/ls, -l, foo, bar. Place the words at the top of the stack. Order doesn't matter, because they will be referenced through pointers.

Then, push the address of each string plus a null pointer sentinel, on the stack, in right-to-left order. These are the elements of argv. The null pointer sentinel ensures that argv[argc] is a null pointer, as required by the C standard. The order ensures that argv[0] is at the lowest virtual address. The x86 ABI requires that %esp be aligned to a 16-byte boundary at the time the call instruction is executed (e.g., at the point where all arguments are pushed to the stack), so make sure to leave enough empty space on the stack so that this is achieved.

Then, push argv (the address of argv[0]) and argc, in that order. Finally, push a fake "return address": although the entry function will never return, its stack frame must have the same structure as any other.

The table below shows the state of the stack and the relevant registers right before the beginning of the user program, assuming PHYS_BASE is 0xc0000000:

Address	Name	Data	Type
0xbffffffc	argv[3][]	$\mathtt{bar} ackslash 0$	char[4]
0xbffffff8	argv[2][]	$foo \setminus 0$	char[4]
0xbffffff5	argv[1][]	-1\0	char[3]
0xbfffffed	argv[0][]	/bin/ls $ackslash 0$	char[8]
Oxbfffffec	stack-align	0	uint8_t
0xbfffffe8	argv[4]	0	char *
0xbfffffe4	argv[3]	0xbffffffc	char *
0xbfffffe0	argv[2]	0xbffffff8	char *
0xbfffffdc	argv[1]	0xbffffff5	char *
0xbfffffd8	argv[0]	0xbfffffed	char *
0xbfffffd4	argv	0xbfffffd8	char **
0xbfffffd0	argc	4	int
0xbfffffcc	return address	0	void (*) ()

In this example, the stack pointer would be initialized to Oxbfffffcc.

As shown above, your code should start the stack at the very top of the user virtual address space, in the page just below virtual address PHYS_BASE (defined in threads/vaddr.h).

You may find the non-standard hex_dump() function, declared in <stdio.h>, useful for debugging your argument passing code. Here's what it would show in the above example:

```
bfffffc0 00 00 00 00 | ....|

bfffffd0 04 00 00 00 d8 ff ff bf-ed ff ff bf f5 ff ff bf |..................|

bfffffe0 f8 ff ff bf fc ff ff bf-00 00 00 00 2f 62 69 |............../bi|

bffffff0 6e 2f 6c 73 00 2d 6c 00-66 6f 6f 00 62 61 72 00 |n/ls.-l.foo.bar.|
```

4.1.7 Adding New Tests to Pintos

Pintos also comes with its own testing framework that allows you to design and run your own tests. For this project, you will also be required to extend the current suite of tests with a few tests of your own. All of the file system and userprog tests are "user program" tests, which means that they are only allowed to interact with the kernel via system calls.

Some things to keep in mind while writing your test cases:

- User programs have access to a limited subset of the C standard library. You can find the user library in lib/.
- User programs cannot directly access variables in the kernel.
- User programs do not have access to malloc, since brk and sbrk are not implemented. User programs also have a limited stack size. If you need a large buffer, make it a static global variable.
- Pintos starts with 4 MB of memory and the file system block device is 2 MB by default. Don't use data structures or files that exceed these sizes.
- Your test should use msg() instead of printf() (they have the same function signature).

You can add new test cases to the userprog suite by modifying these files:

tests/userprog/Make.tests Entry point for the userprog test suite. You need to add the name of your test to the tests/userprog_TESTS variable, in order for the test suite to find it. Additionally, you will need to define a variable named tests/userprog/my-test-1_SRC which contains all the files that need to be compiled into your test (see the other test definitions for examples). You can add other source files and resources to your tests, if you wish.

- tests/userprog/my-test-1.c This is the test code for your test. Your test should define a function called test_main, which contains a user-level program. This is the main body of your test case, which should make syscalls and print output. Use the msg() function instead of printf.
- tests/userprog/my-test-1.ck Every test needs a .ck file, which is a Perl script that checks the output of the test program. If you are not familiar with Perl, don't worry! You can probably get through this part with some educated guessing. Your check script should use the subroutines that are defined in tests/tests.pm. At the end, call pass to print out the "PASS" message, which tells Pintos test driver that your test passed.

4.2 System Calls

4.2.1 System Call Overview

One way that the operating system can regain control from a user program is **external interrupts** from timers and I/O devices. These are "external" interrupts, because they are caused by entities outside the CPU. The operating system also deals with **software exceptions**, which are events that occur in program code. These can be errors such as a page fault or division by zero. Exceptions are also the means by which a user program can request services ("system calls") from the operating system.

In the 80x86 architecture, the int instruction is the most commonly used means for invoking system calls. This instruction is handled in the same way as other software exceptions. In Pintos, user programs invoke int \$0x30 to make a system call. The system call number and any additional arguments are expected to be pushed on the stack in the normal fashion before invoking the interrupt (see section 80x86 Calling Convention).

Thus, when the system call handler syscall_handler() gets control, the system call number is in the 32-bit word at the caller's stack pointer, the first argument is in the 32-bit word at the next higher address, and so on. The caller's stack pointer is accessible to syscall_handler() as the esp member of the struct intr_frame passed to it. (struct intr_frame is on the kernel stack.)

The 80x86 convention for function return values is to place them in the eax. register. System calls that return a value can do so by modifying the eax member of struct intr_frame.

You should try to avoid writing large amounts of repetitive code for implementing system calls. Each system call argument, whether an integer or a pointer, takes up 4 bytes on the stack. You should be able to take advantage of this to avoid writing much near-identical code for retrieving each system call's arguments from the stack.

4.2.2 Process System Calls

For Task 2, you will need to implement the following system calls:

- **System Call: int practice (int i)** A "fake" system call that doesn't exist in any modern operating system. You will implement this to get familiar with the system call interface. This system call increments the passed in integer argument by 1 and returns it to the user.
- System Call: void halt (void) Terminates Pintos by calling shutdown_power_off() (declared in devices/shutdown.h). This should be seldom used, because you lose some information about possible deadlock situations, etc.
- System Call: void exit (int status) Terminates the current user program, returning status to the kernel. If the process's parent waits for it (see below), this is the status that will be returned. Conventionally, a status of 0 indicates success and nonzero values indicate errors. Every user program that finishes in the normal way calls exit—even a program that returns from main() calls exit indirectly (see start() in lib/user/entry.c). In order to make the test suite pass, you need to print out the exit status of each user program when it exits. The code should look like: "printf("%s: exit(%d)\n", thread_current()->name, exit_code);".
- System Call: pid_t exec (const char *cmd_line) Runs the executable whose name is given in cmd_line, passing any given arguments, and returns the new process's program id (pid). Must return pid -1, which otherwise should not be a valid pid, if the program cannot load or run for any reason. Thus, the parent process cannot return from the exec until it knows whether the child process successfully loaded its executable. You must use appropriate synchronization to ensure this.

System Call: int wait (pid_t pid) Waits for a child process pid and retrieves the child's exit status.

If pid is still alive, waits until it terminates. Then, returns the status that pid passed to exit. If pid did not call exit(), but was terminated by the kernel (e.g. killed due to an exception), wait(pid) must return -1. It is perfectly legal for a parent process to wait for child processes that have already terminated by the time the parent calls wait, but the kernel must still allow the parent to retrieve its child's exit status, or learn that the child was terminated by the kernel.

wait must fail and return -1 immediately if any of the following conditions is true:

- pid does not refer to a direct child of the calling process. pid is a direct child of the calling
 process if and only if the calling process received pid as a return value from a successful call
 to exec.
 - Note that children are not inherited: if A spawns child B and B spawns child process C, then A cannot wait for C, even if B is dead. A call to wait(C) by process A must fail. Similarly, orphaned processes are not assigned to a new parent if their parent process exits before they do.
- The process that calls wait has already called wait on pid. That is, a process may wait for any given child at most once.

Processes may spawn any number of children, wait for them in any order, and may even exit without having waited for some or all of their children. Your design should consider all the ways in which waits can occur. All of a process's resources, including its struct thread, must be freed whether its parent ever waits for it or not, and regardless of whether the child exits before or after its parent.

You must ensure that Pintos does not terminate until the initial process exits. The supplied Pintos code tries to do this by calling process_wait() (in userprog/process.c) from main() (in threads/init.c). We suggest that you implement process_wait() according to the comment at the top of the function and then implement the wait system call in terms of process_wait().

Warning: Implementing this system call requires considerably more work than any of the rest.

4.2.3 File System Calls

For task 3, you will need to implement the following system calls:

- System Call: bool create (const char *file, unsigned initial_size) Creates a new file called file initially initial_size bytes in size. Returns true if successful, false otherwise. Creating a new file does not open it: opening the new file is a separate operation which would require a open system call.
- System Call: bool remove (const char *file) Deletes the file called file. Returns true if successful, false otherwise. A file may be removed regardless of whether it is open or closed, and removing an open file does not close it. See Removing an Open File, for details.
- System Call: int open (const char *file) Opens the file called file. Returns a nonnegative integer handle called a "file descriptor" (fd), or -1 if the file could not be opened.

File descriptors numbered 0 and 1 are reserved for the console: fd 0 (STDIN_FILENO) is standard input, fd 1 (STDOUT_FILENO) is standard output. The open system call will never return either of these file descriptors, which are valid as system call arguments only as explicitly described below.

Each process has an independent set of file descriptors. File descriptors are not inherited by child processes.

When a single file is opened more than once, whether by a single process or different processes, each open returns a new file descriptor. Different file descriptors for a single file are closed independently in separate calls to close() and they do not share a file position.

System Call: int filesize (int fd) Returns the size, in bytes, of the file open as fd.

System Call: int read (int fd, void *buffer, unsigned size) Reads size bytes from the file open as fd into buffer. Returns the number of bytes actually read (0 at end of file), or -1 if the file could not be read (due to a condition other than end of file). Fd 0 reads from the keyboard using input_getc().

System Call: int write (int fd, const void *buffer, unsigned size) Writes size bytes from buffer to the open file fd. Returns the number of bytes actually written, which may be less than size if some bytes could not be written.

Writing past end-of-file would normally extend the file, but file growth is not implemented by the basic file system. The expected behavior is to write as many bytes as possible up to end-of-file and return the actual number written, or 0 if no bytes could be written at all.

Fd 1 writes to the console. Your code to write to the console should write all of buffer in one call to putbuf(), at least as long as size is not bigger than a few hundred bytes. (It is reasonable to break up larger buffers.) Otherwise, lines of text output by different processes may end up interleaved on the console, confusing both human readers and our grading scripts.

System Call: void seek (int fd, unsigned position) Changes the next byte to be read or written in open file fd to position, expressed in bytes from the beginning of the file. (Thus, a position of 0 is the file's start.)

A seek past the current end of a file is not an error. A later read obtains 0 bytes, indicating end of file. A later write extends the file, filling any unwritten gap with zeros. (However, in Pintos files have a fixed length until Project 3 is complete, so writes past end of file will return an error.) These semantics are implemented in the file system and do not require any special effort in system call implementation.

System Call: unsigned tell (int fd) Returns the position of the next byte to be read or written in open file fd, expressed in bytes from the beginning of the file.

System Call: void close (int fd) Closes file descriptor fd. Exiting or terminating a process implicitly closes all its open file descriptors, as if by calling this function for each one.

4.3 FAQ

How much code will I need to write? Here's a summary of our reference solution, produced by the diffstat program. The final row gives total lines inserted and deleted; a changed line counts as both an insertion and a deletion.

The reference solution represents just one possible solution. Many other solutions are also possible and many of those differ greatly from the reference solution. Some excellent solutions may not modify all the files modified by the reference solution, and some may modify files not modified by the reference solution.

The kernel always panics when I run pintos -p file -- -q. Did you format the file system (with pintos -f)?

Is your file name too long? The file system limits file names to 14 characters. A command like pintos -p ../../examples/echo -- -q will exceed the limit. Use

 $\verb|pintos -p .../.../examples/echo -a echo -- -q to put the file under the name echo instead.\\$

Is the file system full?

Does the file system already contain 16 files? The base Pintos file system has a 16-file limit.

The file system may be so fragmented that there's not enough contiguous space for your file.

When I run pintos -p ../file --, the file isn't copied. Files are written under the name you refer to them, by default, so in this case the file copied in would be named ../file. You probably want to run pintos -p ../file -a file -- instead.

You can list the files in your file system with pintos -q ls. The base Pintos file system does not support directories.

- All my user programs die with page faults. This will happen if you haven't implemented argument passing (or haven't done so correctly). The basic C library for user programs tries to read argc and argv off the stack. If the stack isn't properly set up, this causes a page fault.
- All my user programs die with system call! You'll have to implement system calls before you see anything else. Every reasonable program tries to make at least one system call (exit()) and most programs make more than that. Notably, printf() invokes the write() system call. The default system call handler just prints system call and handles exit(). Until you have implemented system calls sufficiently, you can use hex_dump() to check your argument passing implementation (see Program Startup Details).
- How can I disassemble user programs? The objdump (80x86) or i386-elf-objdump (SPARC) utility can disassemble entire user programs or object files. Invoke it as objdump -d <file>. You can use GDB's disassemble command to disassemble individual functions.
- Why do many C include files not work in Pintos programs? Can I use libfoo in my Pintos programs? The C library we provide is very limited. It does not include many of the features that are expected of a real operating system's C library. The C library must be built specifically for the operating system (and architecture), since it must make system calls for I/O and memory allocation. (Not all functions do, of course, but usually the library is compiled as a unit.)

If the library makes syscalls (e.g., parts of the C standard library), then they almost certainly will not work with Pintos. Pintos does not support as rich a syscall interfaces as real operating systems (e.g., Linux, FreeBSD), and furthermore, uses a different interrupt number (0x30) for syscalls than is used in Linux (0x80).

The chances are good that the library you want uses parts of the C library that Pintos doesn't implement. It will probably take at least some porting effort to make it work under Pintos. Notably, the Pintos user program C library does not have a malloc() implementation.

- How do I compile new user programs? Modify src/examples/Makefile, then run make.
- Can I run user programs under a debugger? Yes, with some limitations. See the section of this spec on GDB macros.
- What's the difference between tid_t and pid_t? A tid_t identifies a kernel thread, which may have a user process running in it (if created with process_execute()) or not (if created with thread_create()). It is a data type used only in the kernel.

A pid_t identifies a user process. It is used by user processes and the kernel in the exec and wait system calls.

You can choose whatever suitable types you like for tid_t and pid_t. By default, they're both int. You can make them a one-to-one mapping, so that the same values in both identify the same process, or you can use a more complex mapping. It's up to you.

4.3.1 Argument Passing FAQ

- Isn't the top of stack in kernel virtual memory? The top of stack is at PHYS_BASE, typically 0xc0000000, which is also where kernel virtual memory starts. But before the processor pushes data on the stack, it decrements the stack pointer. Thus, the first (4-byte) value pushed on the stack will be at address 0xbffffffc.
- Is PHYS_BASE fixed? No. You should be able to support PHYS_BASE values that are any multiple of 0x10000000 from 0x80000000 to 0xf0000000, simply via recompilation.
- How do I handle multiple spaces in an argument list? Multiple spaces should be treated as one space. You do not need to support quotes or any special characters other than space.
- Can I enforce a maximum size on the arguments list? You can set a reasonable limit on the size of the arguments.

4.3.2 System Calls FAQ

- Can I cast a struct file * to get a file descriptor? Can I cast a struct thread * to a pid_t? You will have to make these design decisions yourself. Most operating systems do distinguish between file descriptors (or pids) and the addresses of their kernel data structures. You might want to give some thought as to why they do so before committing yourself.
- Can I set a maximum number of open files per process? It is better not to set an arbitrary limit. You may impose a limit of 128 open files per process, if necessary.
- What happens when an open file is removed? You should implement the standard Unix semantics for files. That is, when a file is removed any process which has a file descriptor for that file may continue to use that descriptor. This means that they can read and write from the file. The file will not have a name, and no other processes will be able to open it, but it will continue to exist until all file descriptors referring to the file are closed or the machine shuts down.
- How can I run user programs that need more than 4 kB stack space? You may modify the stack setup code to allocate more than one page of stack space for each process. This is not required in this project.
- What should happen if an exec fails midway through loading? exec should return -1 if the child process fails to load for any reason. This includes the case where the load fails part of the way through the process (e.g. where it runs out of memory in the multi-oom test). Therefore, the parent process cannot return from the exec system call until it is established whether the load was successful or not. The child must communicate this information to its parent using appropriate synchronization, such as a semaphore, to ensure that the information is communicated without race conditions.

4.4 Advice

4.4.1 General advice

You should read through and understand as much of the Pintos source code that you mean to modify before starting work on project. In a sense, this is why we have you write a design doc; it should be obvious that you have a good understanding, at the very least at a high level, of files such as process.c. We see groups in office hours who are really struggling due to a conceptual misunderstanding that has informed the way they designed their implementations and thus have caused bugs when trying to actually implement in code.

You should learn to use the advanced features of GDB. For this project, debugging your code usually takes longer than writing it. However, a good understanding of the code you are modifying can help you pinpoint where the error might be; hence, again, we strongly recommend you to read through and understand at least the files you will be modifying in this project (with the caveat that it is a large codebase, so don't overwhelm yourself).

Do not commit and/or push binary files or unneeded log files. Points will be docked for this for code style.

These projects are designed to be difficult and even push you to your limits as a system programmer, so plan to be busy the next three weeks, and have fun!

4.4.2 Group work

In the past, many groups divided each assignment into pieces. Then, each group member worked on his or her piece until just before the deadline, at which time the group reconvened to combine their code and submit. This is a bad idea. We do not recommend this approach. Groups that do this often find that two changes conflict with each other, requiring lots of last-minute debugging. Some groups who have done this have turned in code that did not even compile or boot, much less pass any tests.

Instead, we recommend integrating your team's changes early and often, using git. This is less likely to produce surprises, because everyone can see everyone else's code as it is written, instead of just when it is finished. These systems also make it possible to review changes and, when a change introduces a bug, drop back to working versions of code.

We also encourage you to program in pairs, or even as a group. Having multiple sets of eyes looking at the same code can help avoid/spot subtle bugs.
