Discussion 4

Max Product

Write a function that takes in a list and returns the maximum product that can be formed using non-consecutive elements of the list. All numbers in the input list are greater than or equal to 1.

```
def max_product(s):  
    """Return the maximum product that can be  
    formed using non-consecutive elements of s.  
  
    >>> max_product([10, 3, 1, 9, 2]) # 10 * 9  
    90  
    >>> max_product([5, 10, 5, 10, 5]) # 5 * 5 * 5  
    125  
    >>> max_product([])  
    1  
    """"  
  
    if len(s) == 0:  
        return 1  
    elif len(s) == 1:  
        return s[0]  
    else:  
        return _____
```

A tip for finding a recursive process:

1. Pick an example: $s = [5, 10, 5, 10, 5]$
2. Write down what recursive calls will do:
 - $\text{max_product}([10, 5, 10, 5]) \rightarrow 10 * 10$
 - $\text{max_product}([5, 10, 5]) \rightarrow 5 * 5$
 - $\text{max_product}([10, 5]) \rightarrow 10$
 - $\text{max_product}([5]) \rightarrow 5$
3. Which one helps build the result?

Either include $s[0]$ but not $s[1]$, OR
Don't include $s[0]$

Choose the larger of:
multiplying $s[0]$ by the max_product of $s[2:]$ (skipping $s[1]$) OR
just the max_product of $s[1:]$ (skipping $s[0]$)

$\text{max}(s[0] * \text{max_product}(s[2:]), \text{max_product}(s[1:]))$

Sum Fun

Implement `sums(n, m)`, which takes a total `n` and maximum `m`. It returns a list of all lists:

- that sum to `n`,
- that contain only positive numbers up to `m`, and
- in which no two adjacent numbers are the same.

```
>>> sums(5, 3)
[[1, 3, 1], [2, 1, 2], [2, 3], [3, 2]]
```

```
>>> sums(5, 5)
[[1, 3, 1], [1, 4], [2, 1, 2], [2, 3], [3, 2], [4, 1], [5]]
```

[1, 3, 1] = [1] + [3, 1]

[2, 1, 2] = [2] + [1, 2]

[2, 3] = [2] + [3]

[3, 2] = [3] + [2]

~~[1, 1, 3]~~ = [1] + [1, 3]

~~[1, 2, 2]~~ = [1] + [2, 2]

```
def sums(n, m):
    if n < 0:
        return []
    if n == 0:
        sums_to_zero = [] # The only way to sum to zero using positives
        return [sums_to_zero] # Return a list of all the ways to sum to zero
    result = []
    for k in range(1, m + 1):
        result = result + [ [k]+rest for rest in sums(n-k,m) if rest == [] or k != rest[0] ]
    return result
```

Slicing Practice

Spring 2023 Midterm 2 Question

Definition. A *prefix sum* of a sequence of numbers is the sum of the first n elements for some positive length n .

(a) (4.0 points)

Implement `prefix`, which takes a list of numbers `s` and returns a list of the prefix sums of `s` in increasing order of the length of the prefix.

```
def prefix(s):  
    """Return a list of all prefix sums of list s.
```

```
>>> prefix([1, 2, 3, 0, 4, 5])
```

```
[1, 3, 6, 6, 10, 15]
```

```
>>> prefix([2, 2, 2, 0, -5, 5])
```

```
[2, 4, 6, 6, 1, 6]
```

```
"""      sum(s[:k+1])      range(len(s))
```

```
return [_____ for k in _____]
```

(a)

(b)

ii. (1.0 pt) Fill in blank (b).

`s`

`[s]`

`s[1:]`

`range(s)`

`range(len(s))`

Tree Recursion with Strings

Parking

Definition. When parking vehicles in a row, a motorcycle takes up 1 parking spot and a car takes up 2 adjacent parking spots. A string of length n can represent n adjacent parking spots using % for a motorcycle, <> for a car, and . for an empty spot.

For example: `'.%%.<><>'` (Thanks to the Berkeley Math Circle for introducing this question.)

Implement `park`, which returns a list of all the ways, represented as strings, that vehicles can be parked in n adjacent parking spots for positive integer n . Spots can be empty.

```
def park(n):  
    """Return the ways to park cars and motorcycles in n adjacent spots.  
    >>> park(1)  
    ['%', '.']  
    >>> park(2)  
    ['%%', '%.', '.%', '..', '<>']  
    >>> len(park(4)) # some examples: '<><>', '.%%.', '%<>%', '%.<>'  
    29  
    """  
    if n < 0:  
        return []  
    elif n == 0:  
        return ['']  
    else:  
        return ['%' + s for s in park(n-1)] + ['. ' + s for s in park(n-1)] + ['<>' + s for s in park(n-2)]
```

```
park(3):  
    %%%  
    %%.  
    %%.  
    %..  
    %<>  
    -----  
    .%%  
    .%.  
    ..%  
    ...  
    .<>  
    -----  
    <>%  
    <>.
```

Dictionaries

```
{'Dem': 0}
```

Dictionary Comprehensions

```
{<key exp>: <value exp> for <name> in <iter exp> if <filter exp>}
```

```
Short version: {<key exp>: <value exp> for <name> in <iter exp>}
```

Data Abstraction

Data Abstraction

A small set of functions enforce an abstraction barrier between *representation* and *use*

- How data are represented (as some underlying list, dictionary, etc.)
- How data are manipulated (as whole values with named parts)

E.g., refer to the parts of a line (affine function) called `f`:

- `slope(f)` instead of `f[0]` or `f['slope']`
- `y_intercept(f)` instead of `f[1]` or `f['y_intercept']`

Why? Code becomes easier to read & revise; later you could represent a line `f` as two points instead of a `[slope, intercept]` pair without changing code that uses lines.
