## 1 Pre-Check

This section is designed as a conceptual check for you to determine if you conceptually understand and have any misconceptions about this topic. Please answer true/false to the following questions, and include an explanation:

- 1.1 After calling a function and having that function return, the t registers may have been changed during the execution of the function, while a registers cannot.
- 1.2 Let a0 point to the start of an array x. lw s0, 4(a0) will always load x[1] into s0.
- 1.3 Assuming no compiler or operating system protections, it is possible to have the code jump to data stored at 0(a0) and execute instructions from there.
- 1.4 Adding the character 'd' to the address of an integer array would get you the element at index 25 of that array (assuming the array is large enough).
- [1.5] Calling jalr is a shorthanded expression for jal that jumps to the specified label and does not store a return address anywhere.
- [1.6] Calling j label does the exact same thing as calling jal label.

#### 2 RISC-V: A Rundown

RISC-V is an assembly language, which is comprised of simple instructions that each do a single task such as addition or storing a chunk of data to memory.

For example, on the left is a line of C code and on the right is a chunk of RISC-V code that accomplishes the same thing.

```
// x -> s0, &y -> s1

int x = 5, y[2]; addi s0, x0, 5

y[0] = x; sw s0, 0(s1)

y[1] = x * x; mul t0, s0, s0

sw t0, 4(s1)
```

[2.1] Can you figure out what each line in the RISC-V code is doing?

#### 3 Registers

In RISC-V, we have two methods of storing data: main memory and registers. Registers are much faster than using main memory, but are very limited in space (32 bits each). Note that you should ALWAYS use the named registers (e.g.  $\mathfrak{s0}$  rather than  $\mathfrak{x8}$ ).

Register(s)	Alt.	Description
x0	zero	The zero register, always zero
x1	ra	The return address register, stores where functions should return
x2	$^{\mathrm{sp}}$	The stack pointer, where the stack ends
x5-x7, x28-x31	t0-t6	The temporary registers
x8-x9, x18-x27	s0-s11	The saved registers
x10-x17	a0-a7	The argument registers, a0-a1 are also return value

[3.1] Can you convert each instruction's registers to the other form?

```
add s0, zero, a1 --> or x18, x1, x30 -->
```

#### 4 Basic Instructions

For your reference, here are some of the basic instructions for arithmetic operations and dealing with memory (Note: ARG1 is argument register 1, ARG2 is argument register 2, and DR is destination register):

[inst]	[destination register] [argument register 1] [argument register 2]
add	Adds the two argument registers and stores in destination register
xor	Exclusive or's the two argument registers and stores in destination register

mul	Multiplies the two argument registers and stores in destination register		
sll	Logical left shifts ARG1 by ARG2 and stores in DR		
srl	Logical right shifts ARG1 by ARG2 and stores in DR		
sra	Arithmetic right shifts ARG1 by ARG2 and stores in DR		
slt/u	If $ARG1 < ARG2$ , stores 1 in DR, otherwise stores 0, u does unsigned comparison		
[inst]	[register] [offset]([register containing base address])		
sw	Stores the contents of the register to the address+offset in memory		
lw	Takes the contents of address+offset in memory and stores in the register		
[inst]	[argument register 1] [argument register 2] [label]		
beq	If $ARG1 == ARG2$ , moves to label		
bne	If ARG1 != ARG2, moves to label		
[inst]	[destination register] [label]		
jal	Stores the next instruction's address into DR and moves to label		

You may also see that there is an "i" at the end of certain instructions, such as addi, slli, etc. This means that ARG2 becomes an "immediate" or an integer instead of using a register. There are also immediates in some other instructions such as **sw** and **lw**. NOTE: The size of an immediate in any given instruction depends on what type of instruction it is (more on this soon!).

4.1 Assume we have an array in memory that contains int\* arr = {1,2,3,4,5,6,0}. Let register s0 hold the address of the element at index 0 in arr. You may assume integers are four-bytes and our values are word-aligned. What do the snippets of RISC-V code do? Assume that all the instructions are run one after the other in the same context.

```
a) lw t0, 12(s0) -->
```

b) sw t0, 
$$16(s0)$$
 -->

### 5 C to RISC-V

[5.1] Translate between the C and RISC-V verbatim.

```
\mathbf{C}
                                       RISC-V
// s0 -> a, s1 -> b
// s2 -> c, s3 -> z
int a = 4, b = 5, c = 6, z;
z = a + b + c + 10;
// s0 -> int * p = intArr;
// s1 -> a;
*p = 0;
int a = 2;
p[1] = p[a] = a;
// s0 -> a, s1 -> b
int a = 5, b = 10;
if(a + a == b) {
   a = 0;
} else {
    b = a - 1;
                                           addi s0, x0, 0
                                           addi s1, x0, 1
                                           addi t0, x0, 30
                                       loop:
                                           beq s0, t0, exit
                                           add s1, s1, s1
                                           addi s0, s0, 1
                                           jal x0, loop
                                       exit:
// s0 -> n, s1 -> sum
// assume n > 0 to start
for(int sum = 0; n > 0; n--) {
  sum += n;
}
```

### 6 RISC-V with Arrays and Lists

Comment what each code block does. Each block runs in isolation. Assume that there is an array, int arr[6] = {3, 1, 4, 1, 5, 9}, which starts at memory address 0xBFFFFF00, and a linked list struct (as defined below), struct 11\* 1st, whose first element is located at address 0xABCD0000. Let s0 contain arr's address 0xBFFFFF00, and let s1 contain 1st's address 0xABCD0000. You may assume integers and pointers are 4 bytes and that structs are tightly packed. Assume that 1st's last node's next is a NULL pointer to memory address 0x00000000.

```
6.1
     lw
        t0, 0(s0)
        t1, 8(s0)
     lw
     add t2, t0, t1
     sw t2, 4(s0)
     loop: beq
               s1, x0, end
6.2
                t0, 0(s1)
           addi t0, t0, 1
                t0, 0(s1)
           SW
           1w
                s1, 4(s1)
           jal x0, loop
      end:
6.3
            add t0, x0, x0
     loop: slti t1, t0, 6
            beq t1, x0, end
            slli t2, t0, 2
            add
                 t3, s0, t2
                 t4, 0(t3)
                 t4, x0, t4
                 t4, 0(t3)
            addi t0, t0, 1
            jal x0, loop
      end:
```

struct ll {
 int val;

}

struct 11\* next;

# 7 RISC-V Calling Conventions

7.1 How do we pass arguments into functions?

[7.3] What is sp and how should it be used in the context of RISC-V functions?

[7.4] Which values need to saved by the caller, before jumping to a function using jal?

[7.5] Which values need to be restored by the callee, before returning from a function?

7.6 In a bug-free program, which registers are guaranteed to be the same after a function call? Which registers aren't guaranteed to be the same?

## 8 Writing RISC-V Functions

8.1 Write a function sumSquare in RISC-V that, when given an integer n, returns the summation below. If n is not positive, then the function returns 0.

$$n^2 + (n-1)^2 + (n-2)^2 + \ldots + 1^2$$

For this problem, you are given a RISC-V function called square that takes in a single integer and returns its square.

First, let's implement the meat of the function: the squaring and summing. We will be abiding by the caller/callee convention, so in what register can we expect the parameter n? What registers should hold square's parameter and return value? In what register should we place the return value of sumSquare?

8.2 Since sumSquare is the callee, we need to ensure that it is not overriding any registers that the caller may use. Given your implementation above, write a prologue and epilogue to account for the registers you used.

# 9 More Translating between C and RISC-V

9.1 Translate between the RISC-V code to C. What is this RISC-V function computing? Assume no stack or memory-related issues, and assume no negative inputs.

С	RISC-V
// a0 -> x, a1 -> y,	Func: addi t0 x0 1
// t0 -> result	Loop: beq a1 x0 Done
	mul t0 t0 a0
	addi a1 a1 -1
	jal x0 Loop
	Done: add a0 t0 x0
	jr ra
